

# Catalytic, Stereoselective Dihalogenation of Alkenes: Challenges and Opportunities

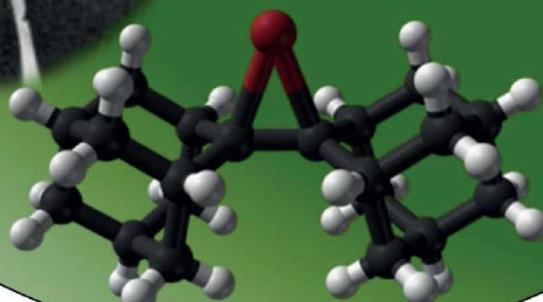

*Alexander J. Cresswell, Stanley T.-C. Eey, and Scott E. Denmark\**

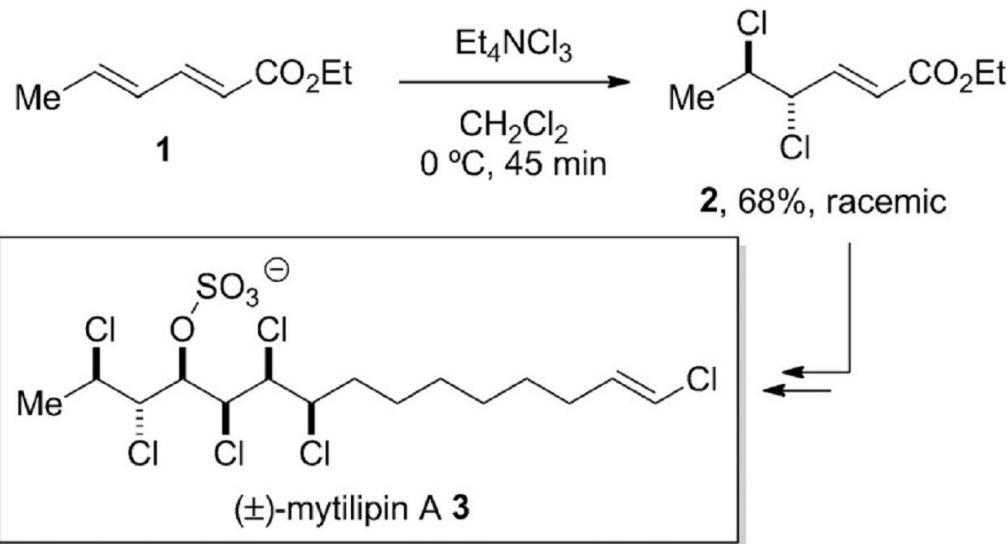

Reporter: Sixuan Meng  
Supervisor: Prof. Huang  
2016-01-09

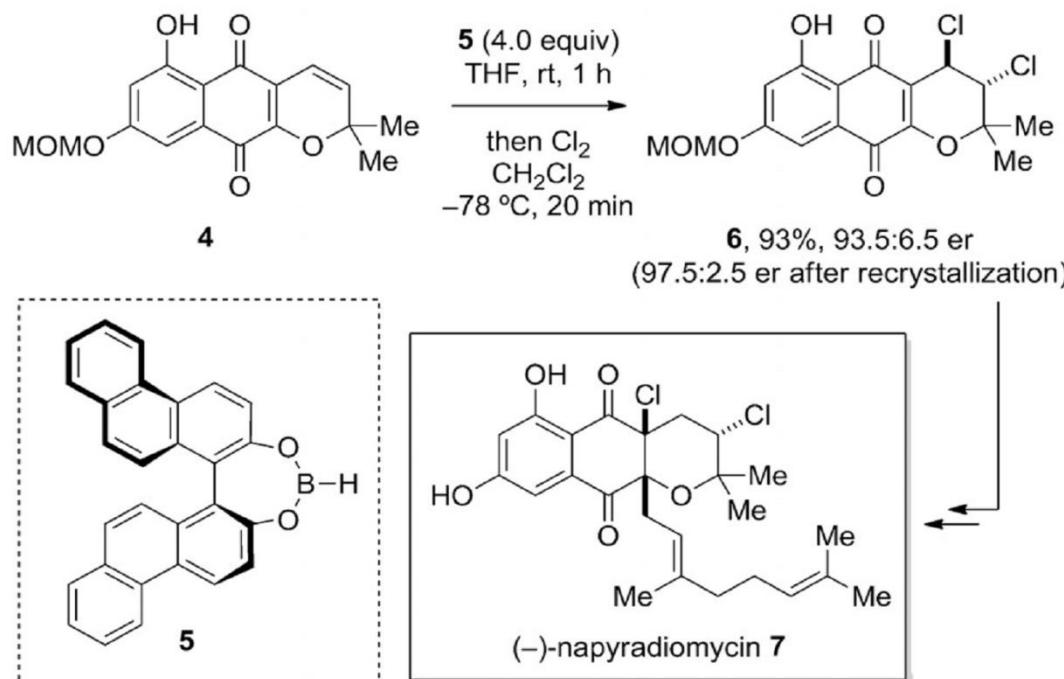

Recent work by Bartlett and Tarbel has shown that the first step in the reaction of halogen molecules with the ethylene linkage leads to the formation of a negative halide ion and a positively charged organic ion..... Another possible structure of the ion is one in which the positive charge is on the halogen. The  $X^+$ , being isoelectronic with a member of the oxygen family, should show a valence of two, i. e., it should form a structure of the ethylene oxide type....

Roberts and Kimball, *J. Am. Chem. Soc.* **1937**,  
59, 946

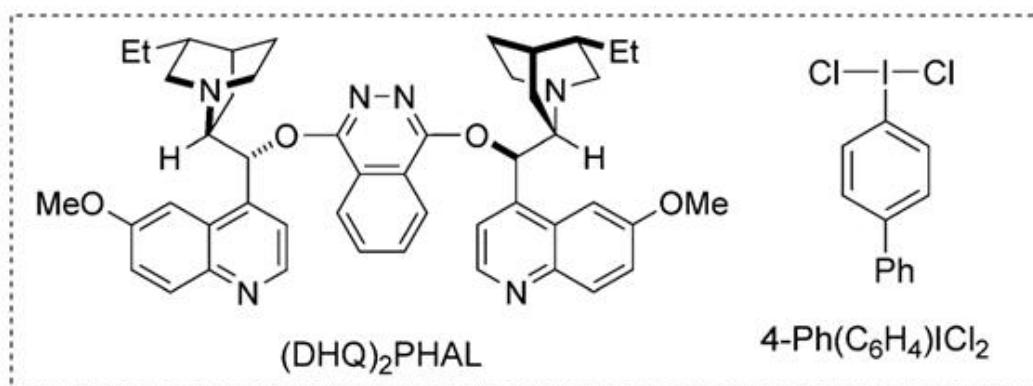

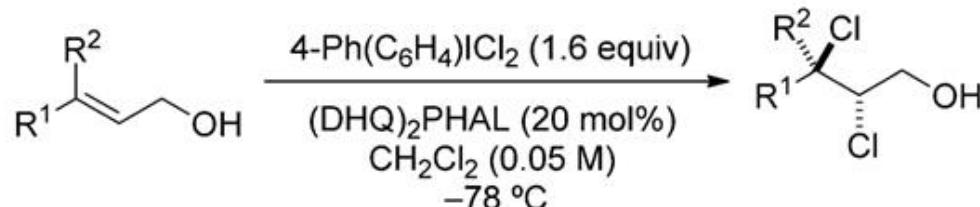

A racemic alkene dichlorination as the first step of Carreira's chlorosulfolipid total synthesis.

## Dichlorination:

## Dibromination:

## \* Challenges for Stereoselective Catalysis

- \*The dihalogenating reagents problem
- \*The catalysis problem
- \*The enantioselectivity problem
- \*The product racemization problem
- \*The diastereocontrol problem

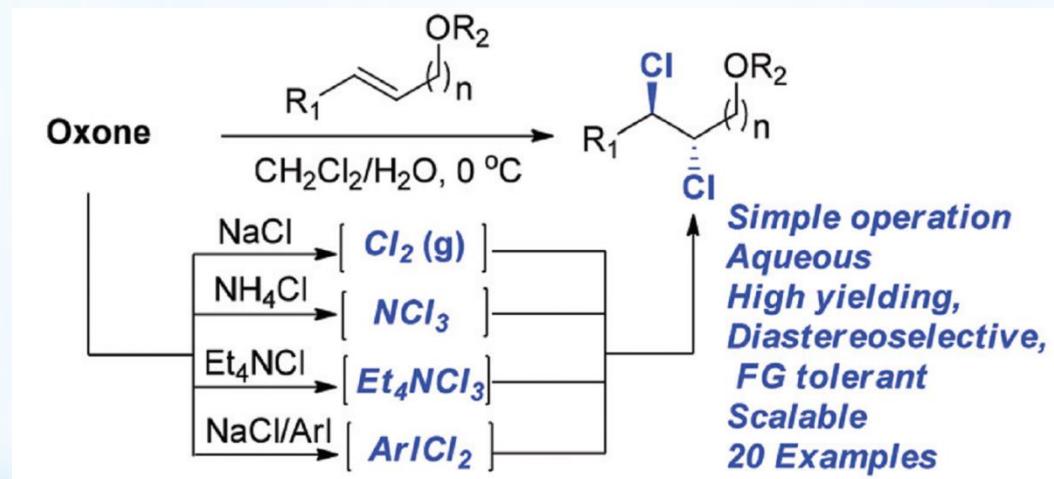

\* “Dihalogen carrier”

eg: ammonium polyhalide salts  $[R_4N]^+[X_2]_n^-$ ,

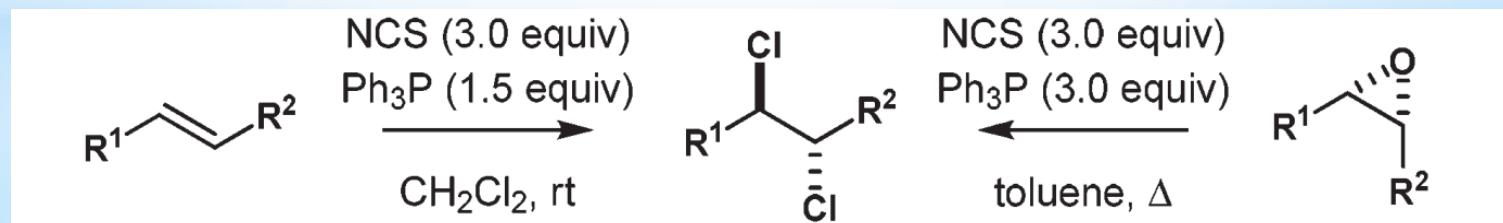

\* In situ generation

halide oxidation:  $H_2O_2$ - $HCl$ ,  $KMnO_4$ - $Me_3SiCl$ - $BnEt_3NCl$ , Oxone-NaCl.

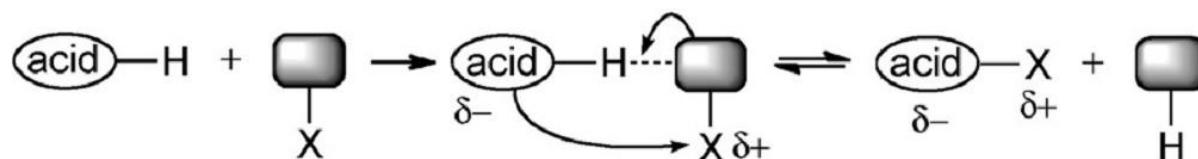

halenium reduction: a 2:1 NCS: $PPh_3$  reagent system

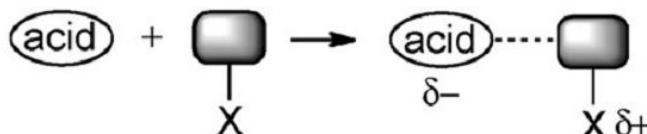

# \* The catalysis problem

## General strategies

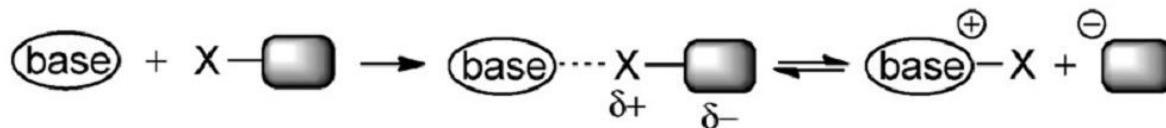

### Brønsted acid

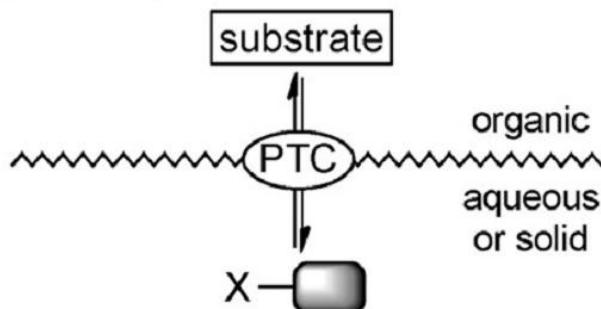

### Lewis acid

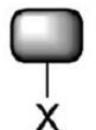

### Lewis base

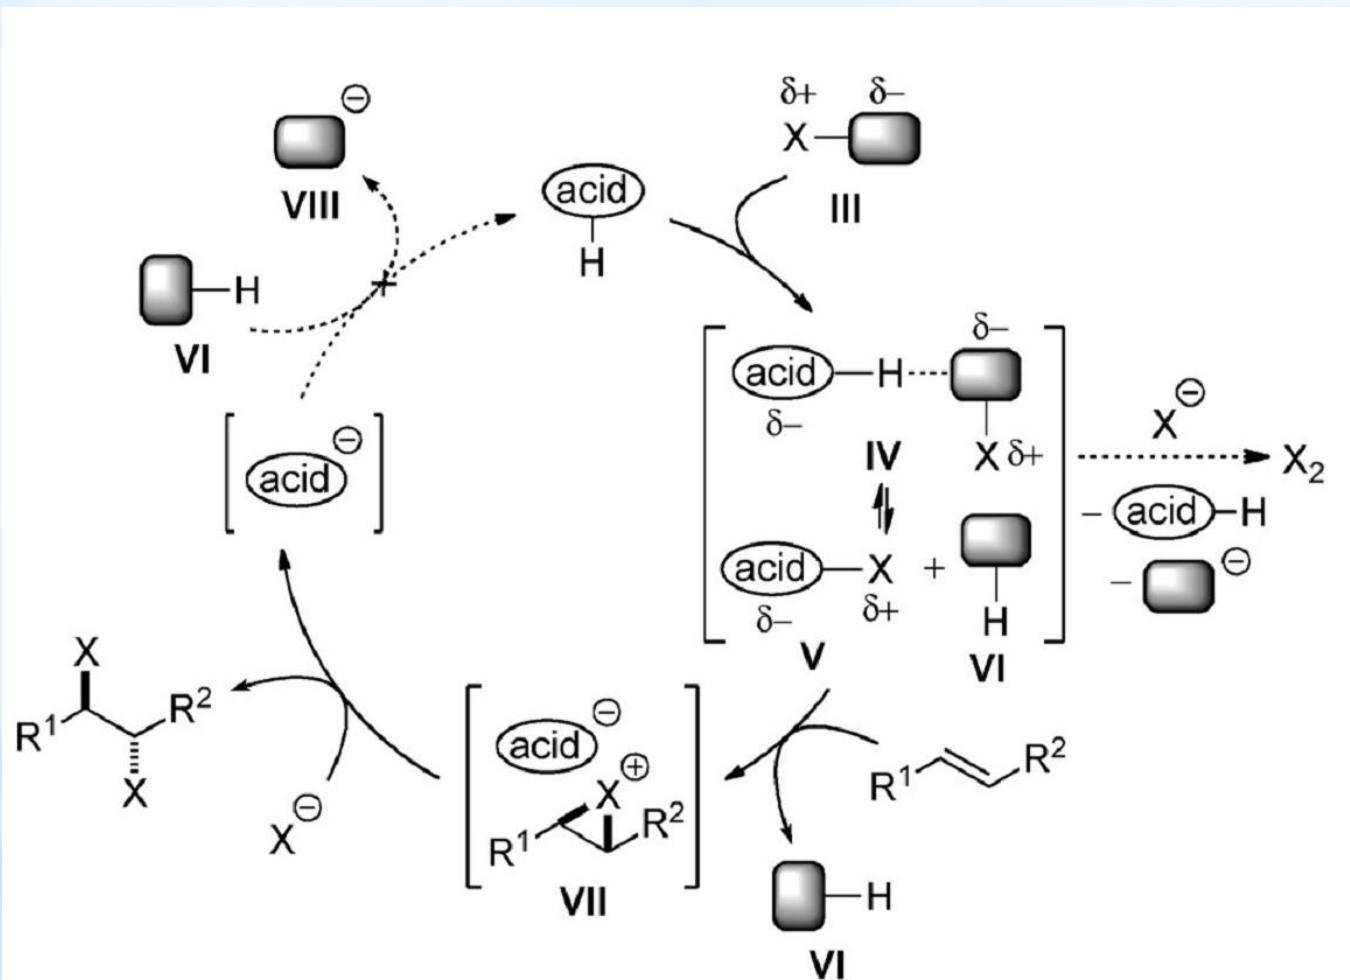

### Phase transfer

 = halogenating agent

## \*Bronsted acid catalysis

**Scheme 11.** A Brønsted acid-catalyzed alkene dihalogenation using separate  $X^+$  and  $X^-$  sources.

## Using a complex anion of the halide as an $X^-$ source.

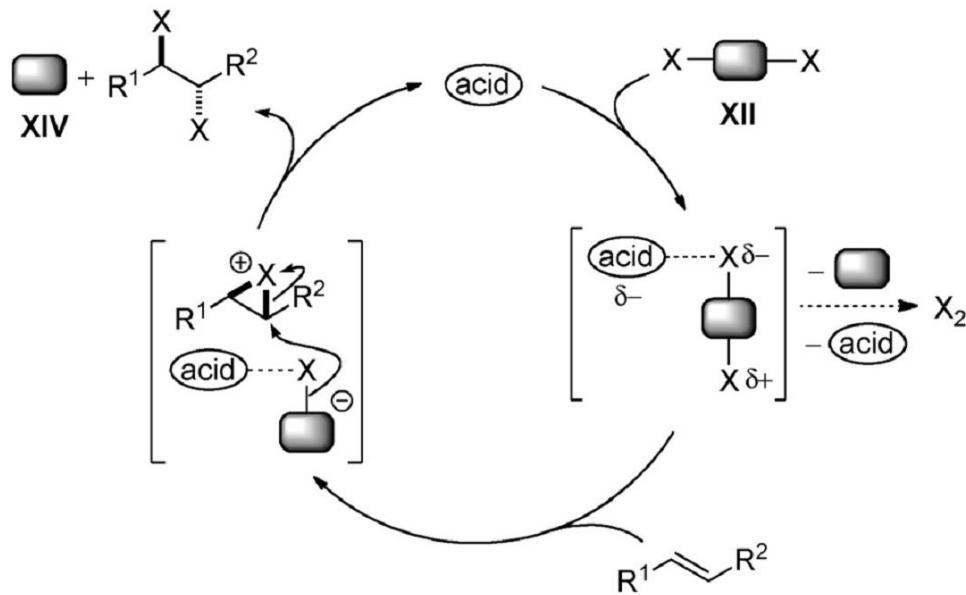

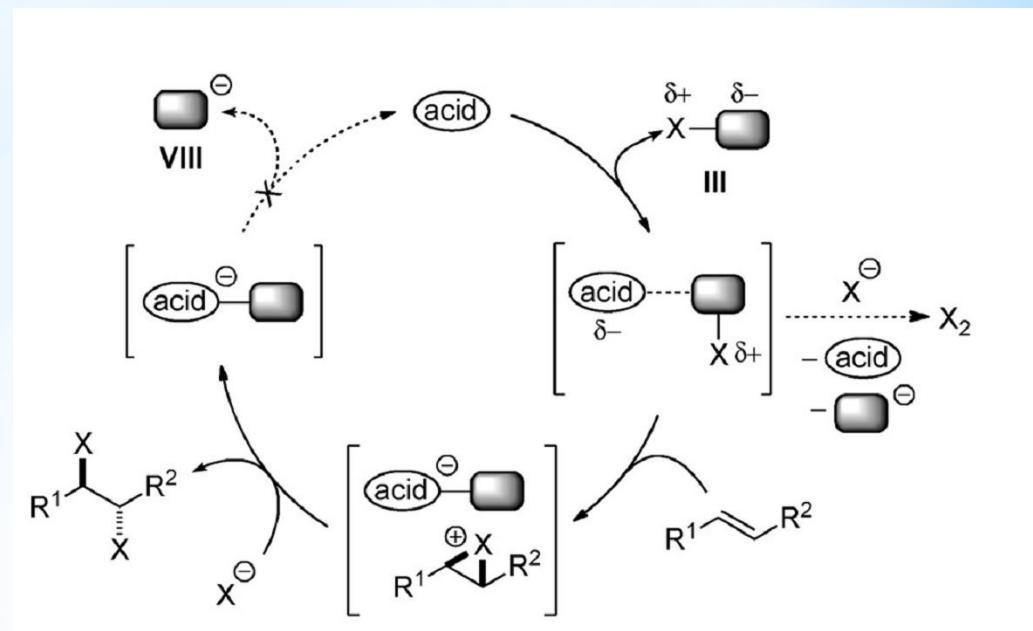

**using a dihalogen equivalent XII as a single reagent.**

**only a neutral by-product XIV is generated**

# \*Lewis acid catalysis

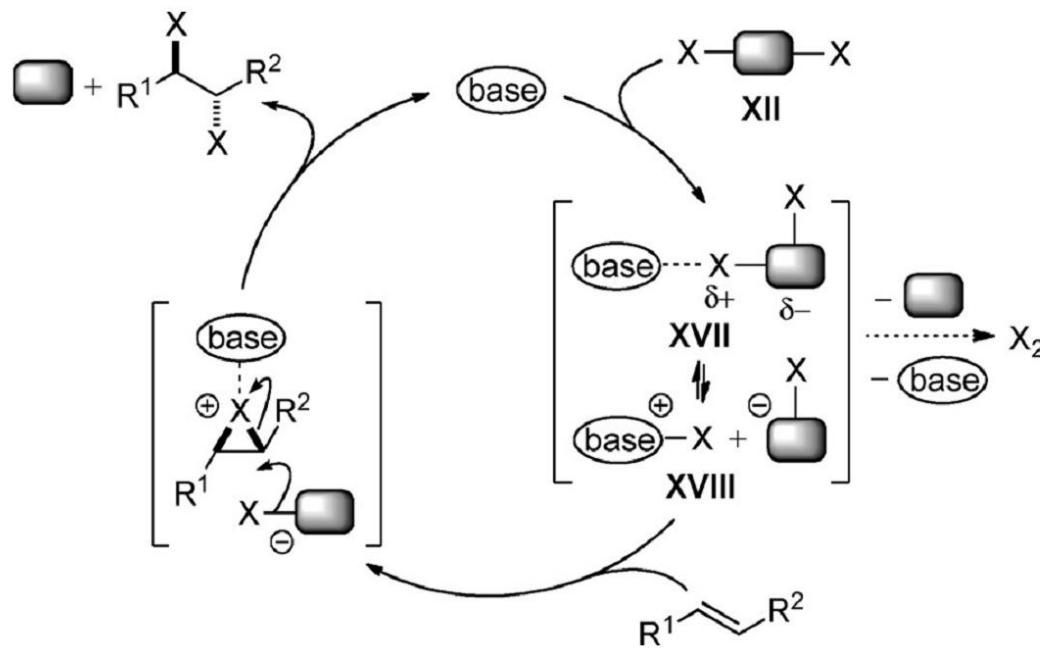

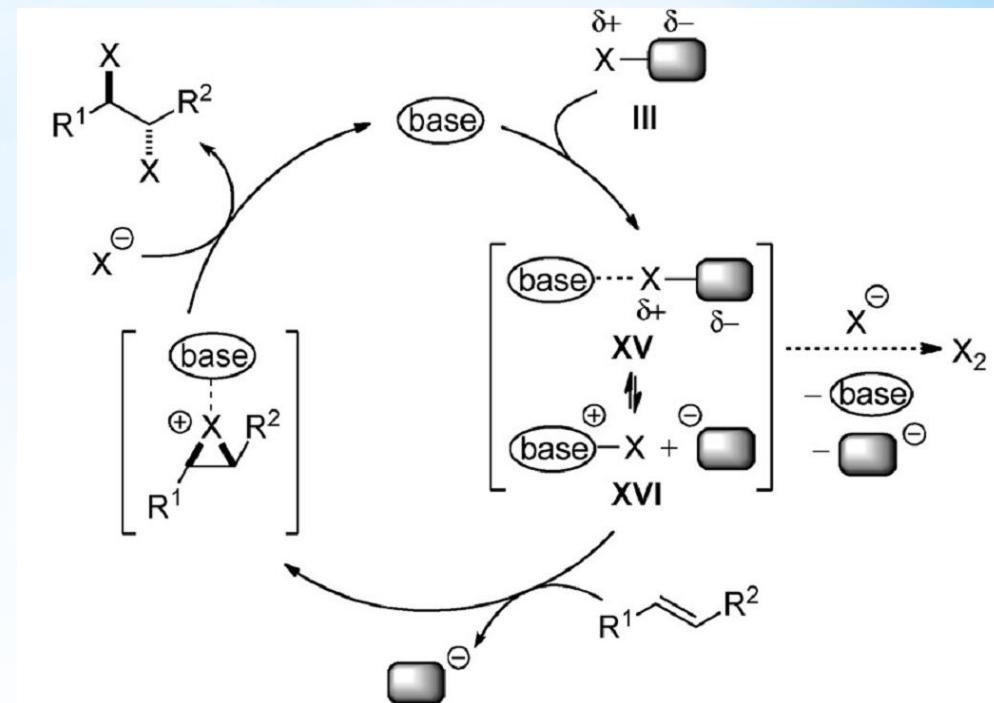

using separate  $X^+$  and  $X^-$  sources

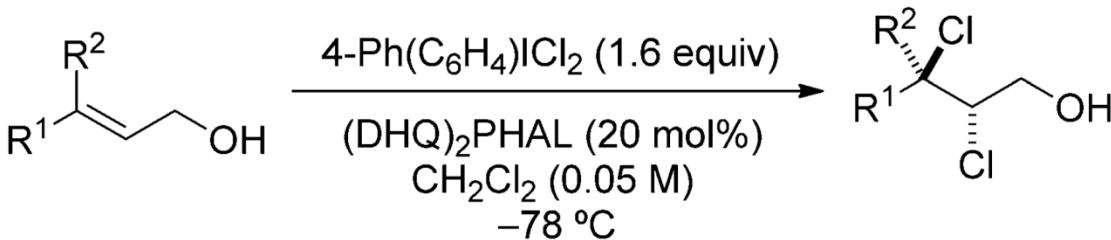

using a dihalogen equivalent XII as a single reagent.

# \*Lewis base catalysis

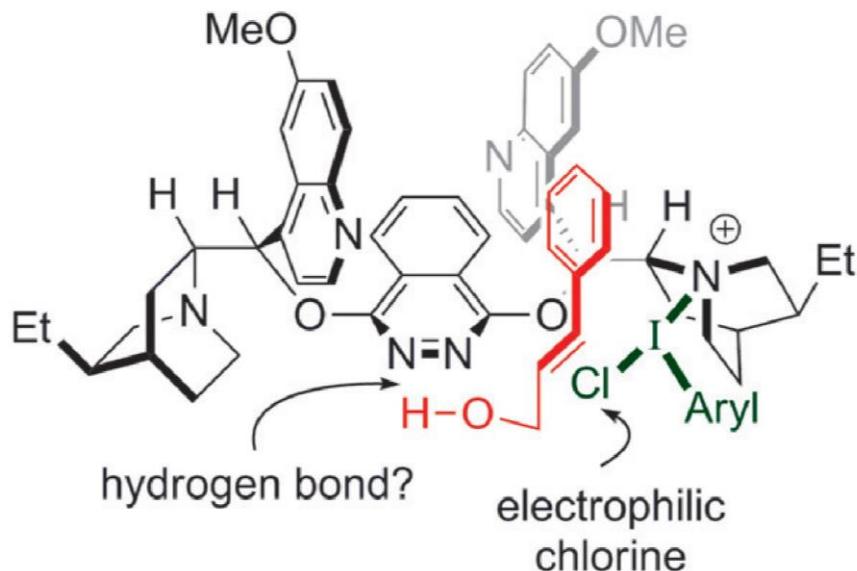

using separate  $X^+$  and  $X^-$  sources

using a dihalogen equivalent XII as a single reagent.

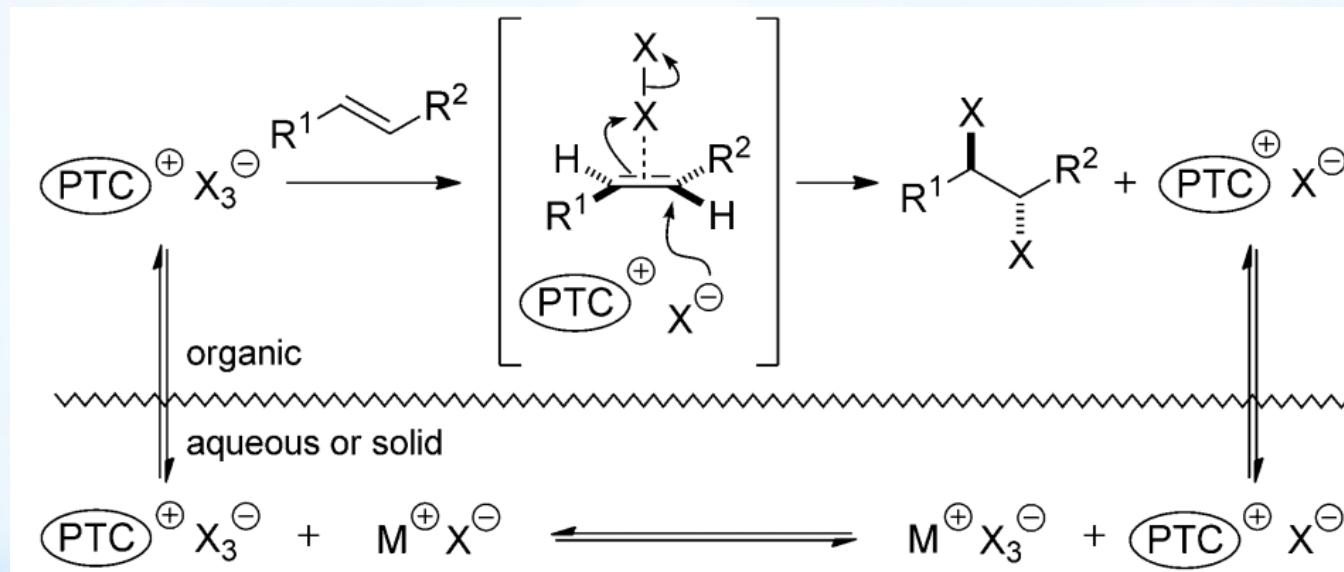

## Proposed stereoinduction model

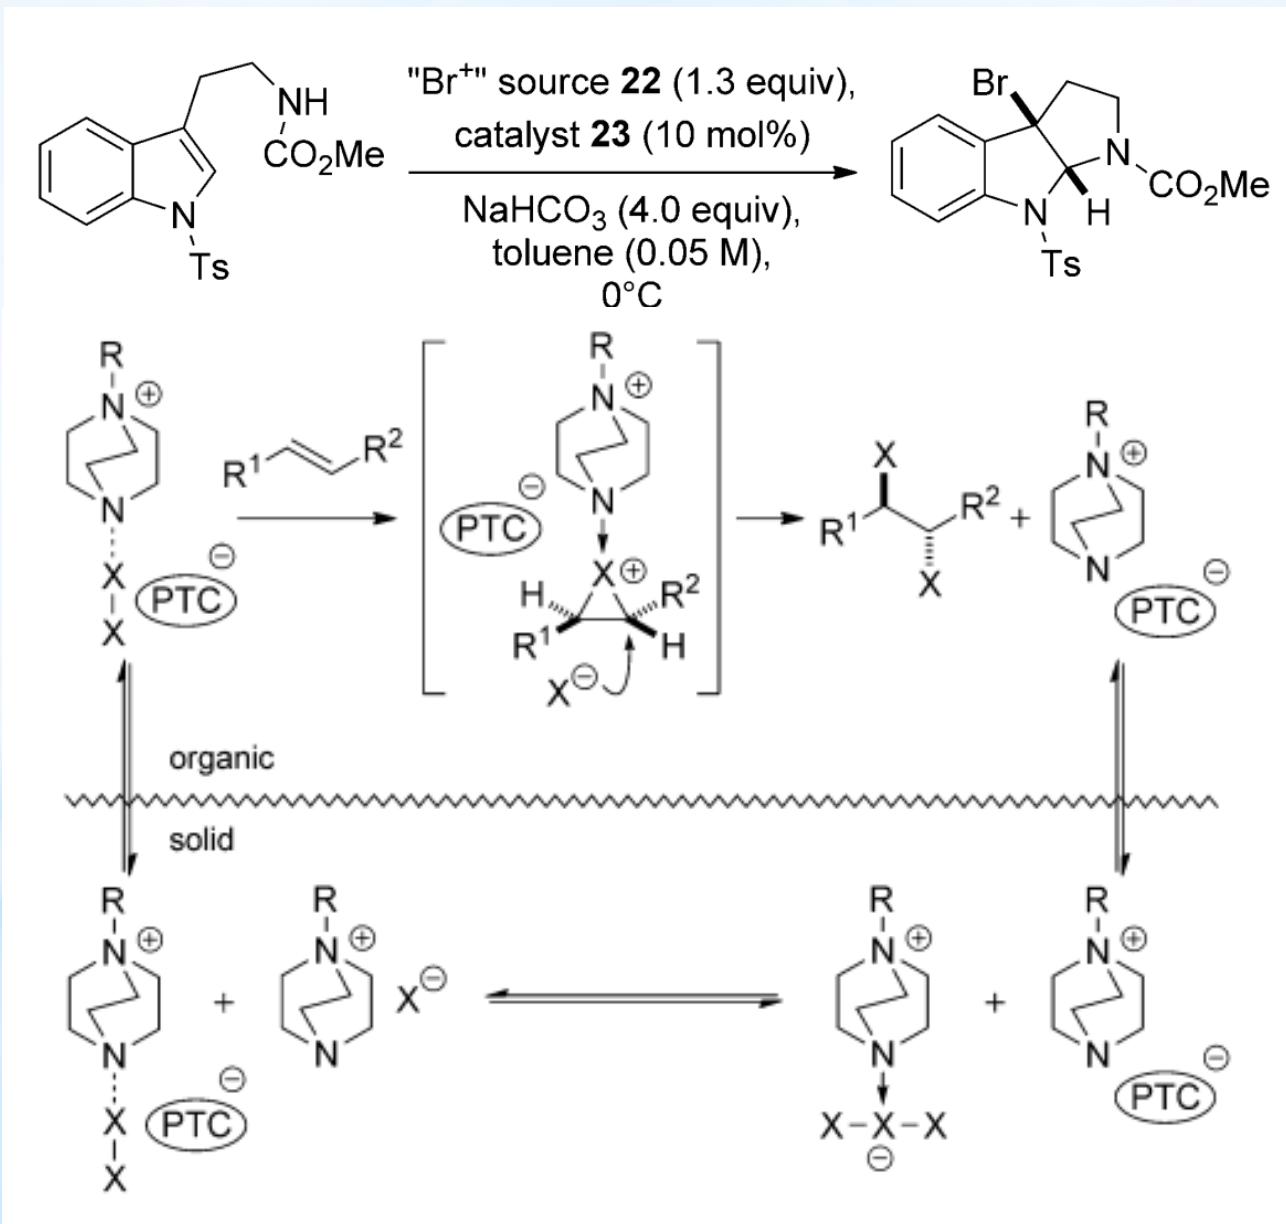

## \*Phase transfer catalysis

### Cationic phase transfer-catalyzed alkene dihalogenation

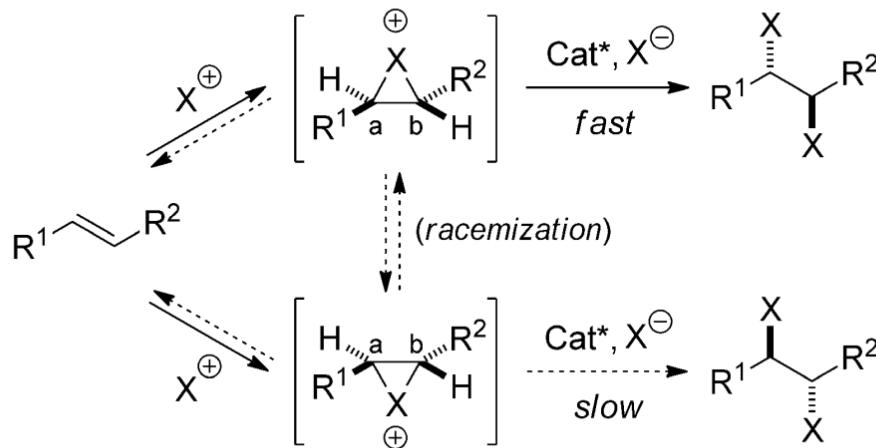

# Chiral anion phase transfer-catalyzed alkene bromocyclization

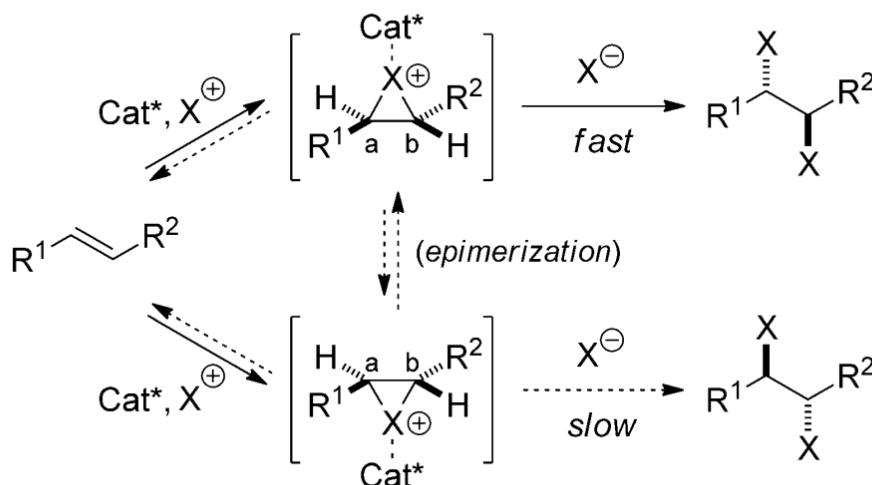

# \*Enantiodetermining nucleophilic trapping

**Dynamic kinetic resolution** (with substrate- or catalyst-controlled halide attack at carbon "a")

Depends on  $k_A/k_B$

**Dynamic kinetic asymmetric transformation (type 1)** (with substrate- or catalyst-controlled halide attack at carbon "a")

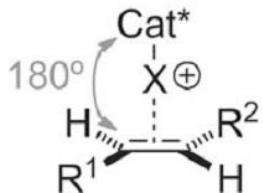

Depends on  $k_A/k_B$ ,  $[\text{I}_A]/[\text{I}_B]$   
e.g.

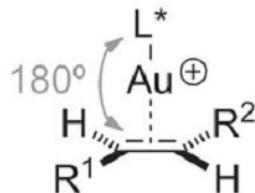

a  $k_A/k_B$  value of 5 in  
combination with  
 $[\text{I}_A]/[\text{I}_B]=4$  would still  
give 20:1 er in favor of A

## \*Enantiodetermining haliranium ion formation

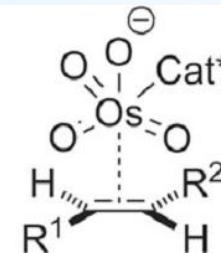

### Haliranium ion formation:

*difficult to relay  
stereochemical information  
via  $\sigma^*$  orbital*

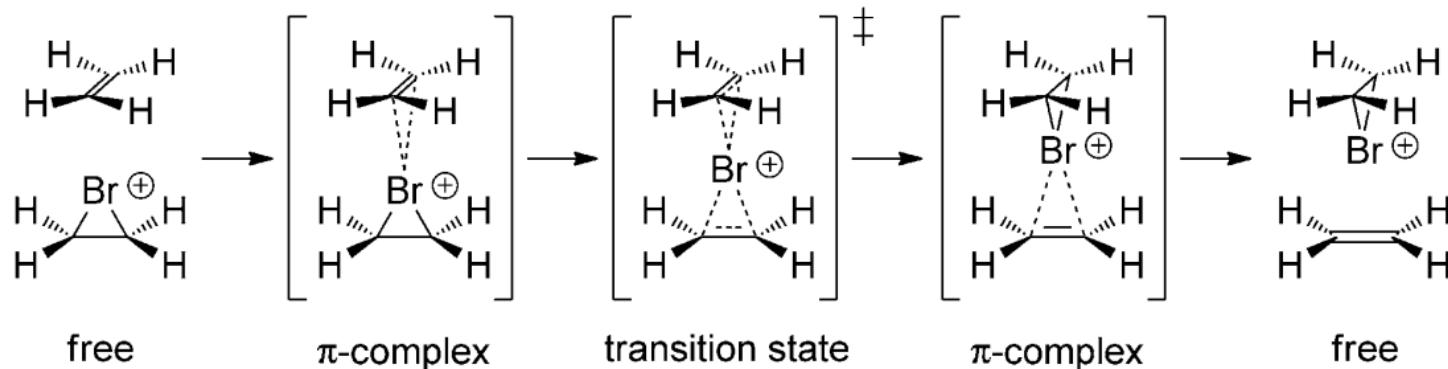

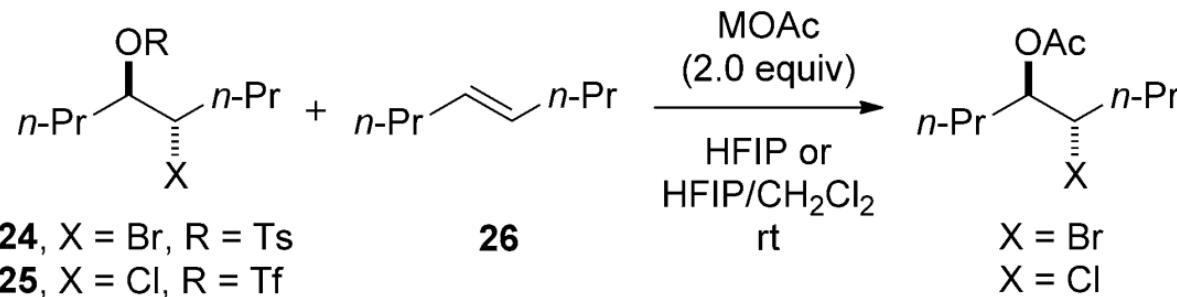

*similar issue in  
Au(I) catalysis due  
to linear  
coordination  
geometry*

*access to  $\pi^*$  enables  
more diverse geometries  
and better stereochemical  
communication*

### Alkene-to-alkene transfer:

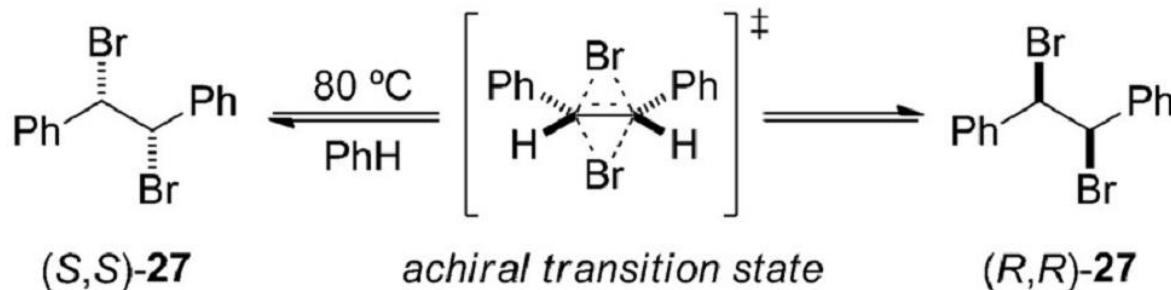

| X  | M                           | <b>26</b> , Equiv | es (%) |
|----|-----------------------------|-------------------|--------|
| Br | Na                          | 0.0               | 100    |
| Br | Na                          | 1.0               | 26     |
| Br | <i>n</i> -Bu <sub>4</sub> N | 1.0               | 81     |
| Cl | <i>n</i> -Bu <sub>4</sub> N | 1.0               | 100    |

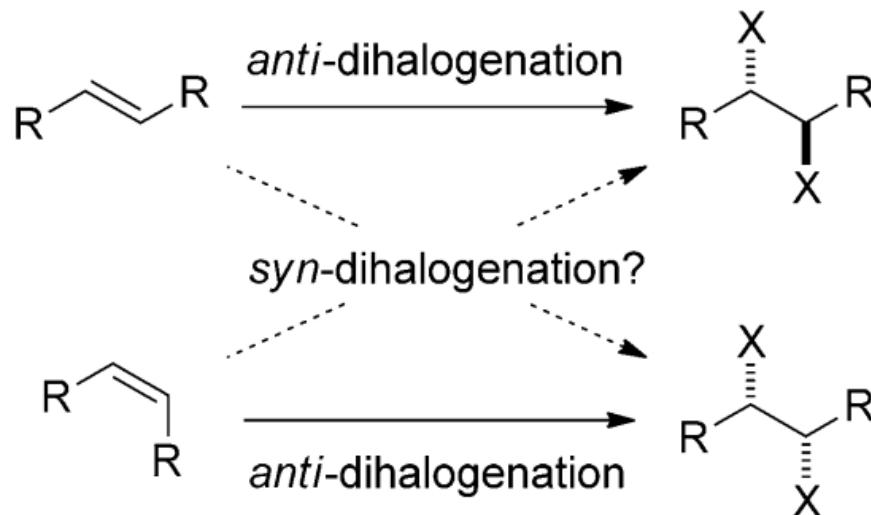

**Scheme 28.** Erosion of enantiospecificity in acetolysis from alkene-to-alkene transfer. HFIP = hexafluoroisopropanol, Tf = trifluoromethane-sulfonyl, Ts = 4-toluenesulfonyl, es =  $(ee_{\text{product}}/ee_{\text{starting material}}) \times 100\%$ .

## \* The product racemization problem

$$k = 0.0015 \text{ s}^{-1}, \Delta G^\ddagger_{353} = 25.3 \text{ kcal mol}^{-1}$$

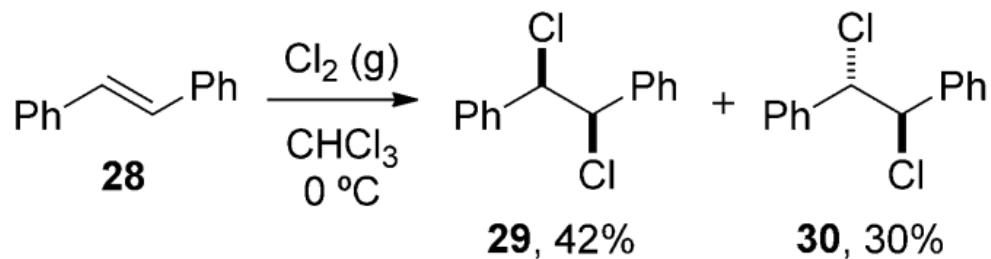

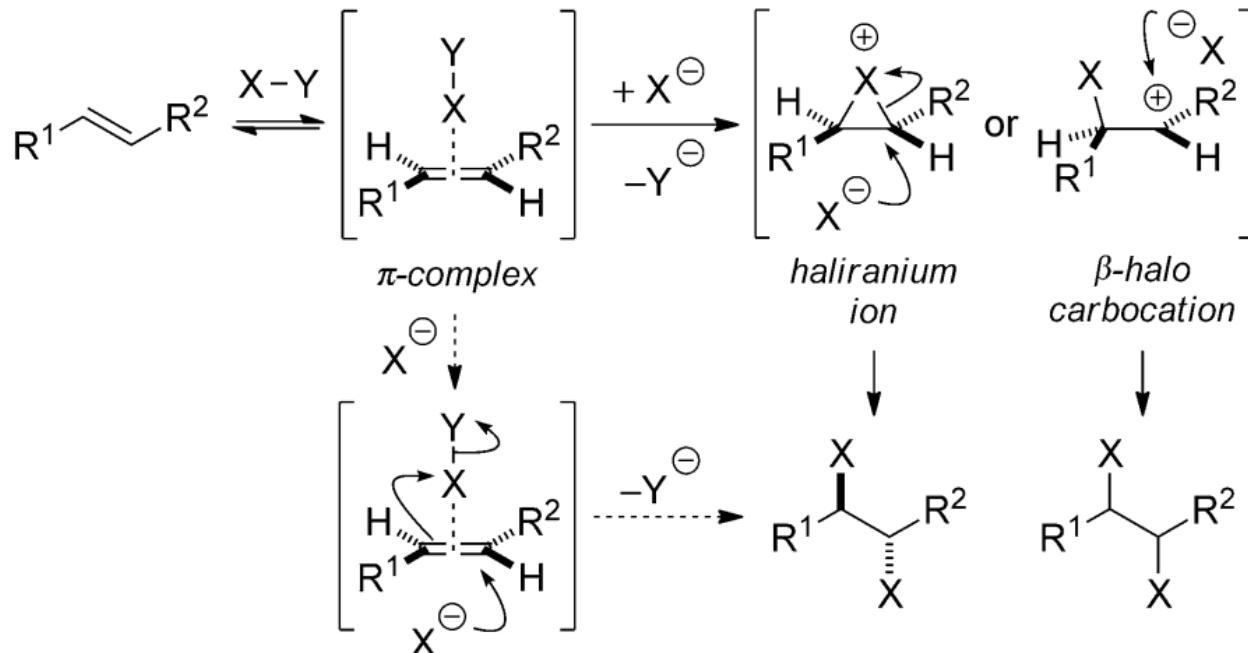

## \* The diastereococontrol problem

## \* Mechanistic Classification of Alkene Dihalogenations

- \* Type I Dihalogenation
- \* Type II Dihalogenation
- \* Type III Dihalogenation
- \* Type IV Dihalogenation
- \* Type V Dihalogenation

## \* Type I Dihalogenation

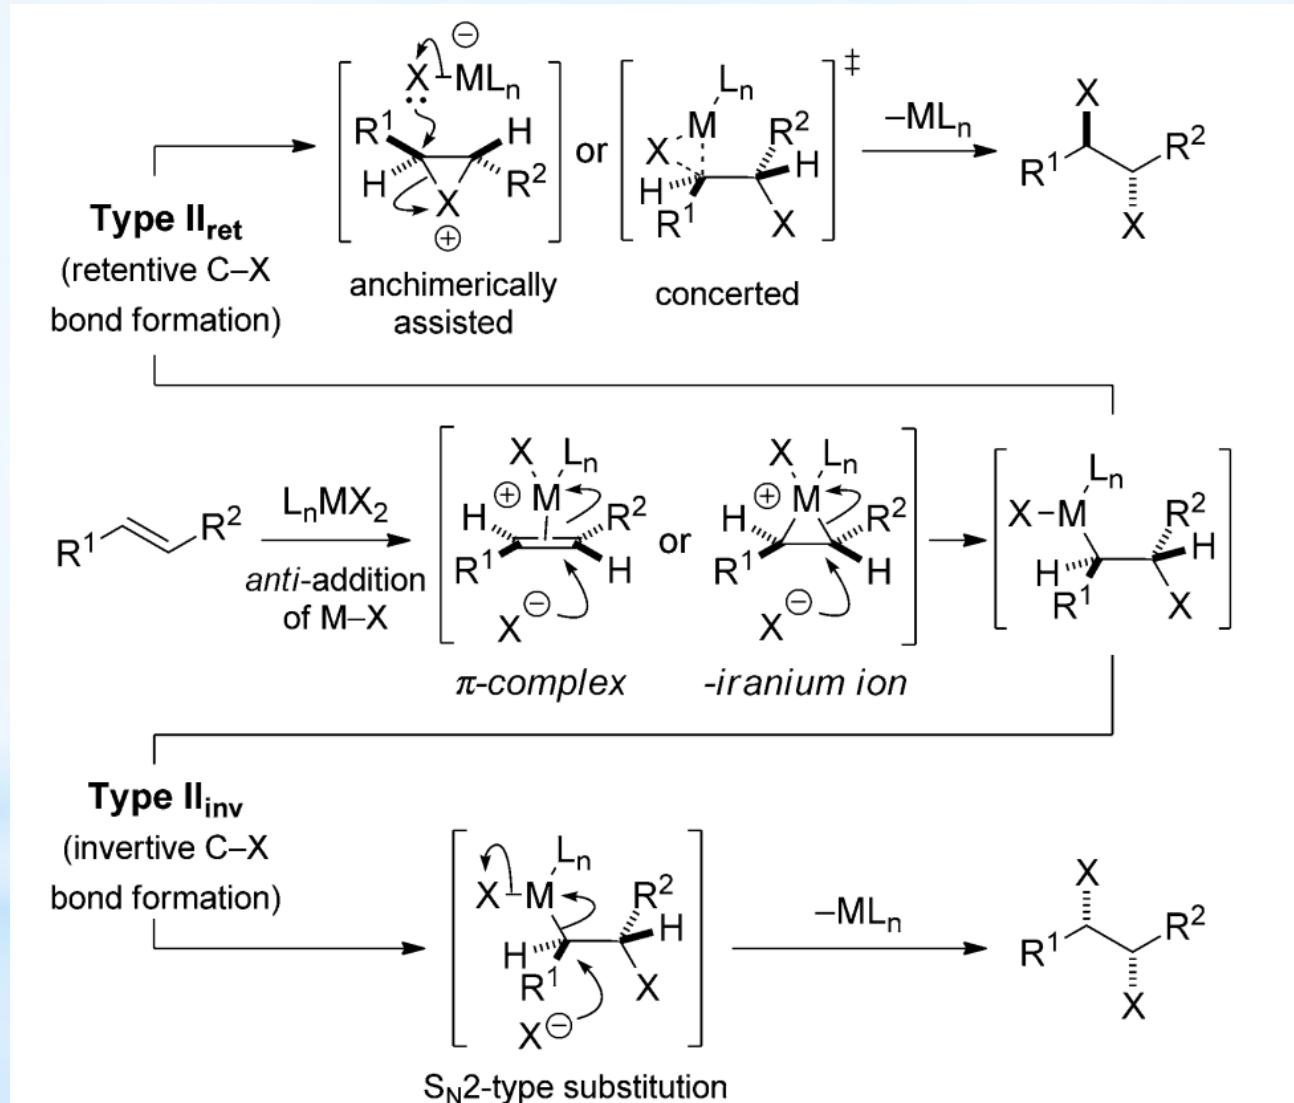

P. B. D. de La Mara *et al.* J. Chem. Soc. 1961, 5285

**Factors to reduce the halogen bridging:**

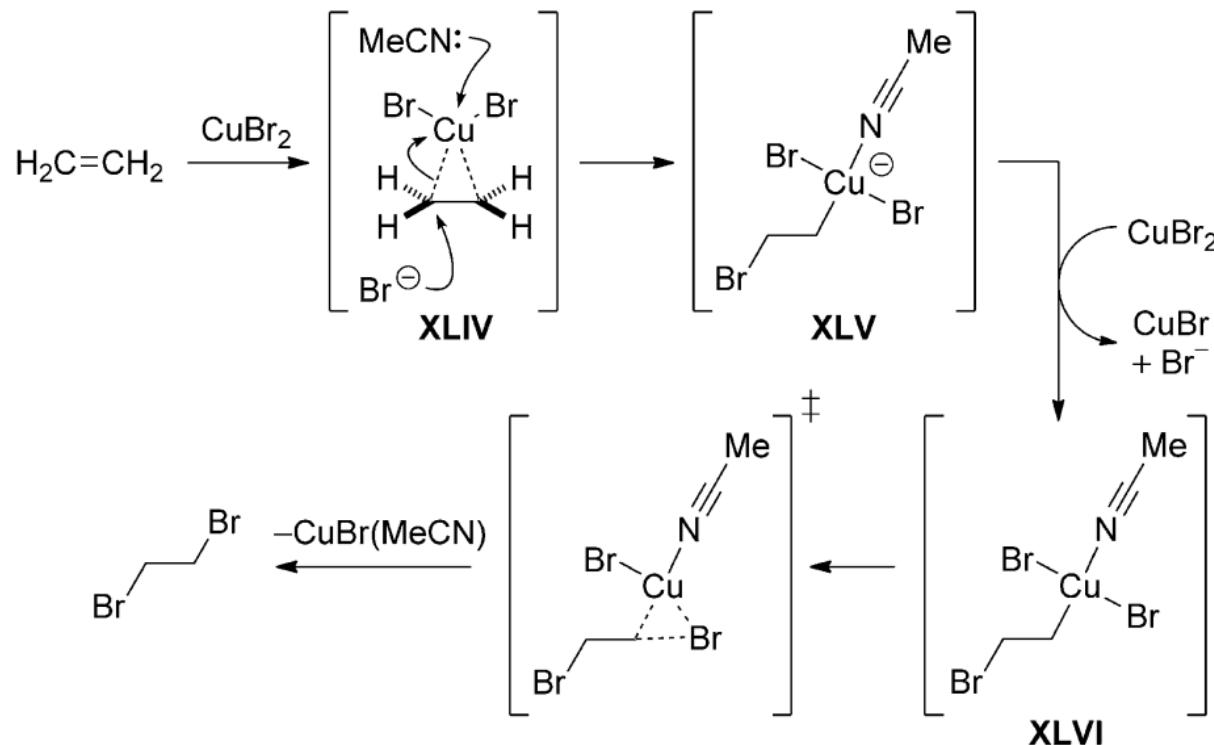

- Cation-stabilizing substituents at one end of the halonium ion
- High dielectric solvents
- Chlorine as the halogen

## \* Type II Dihalogenation

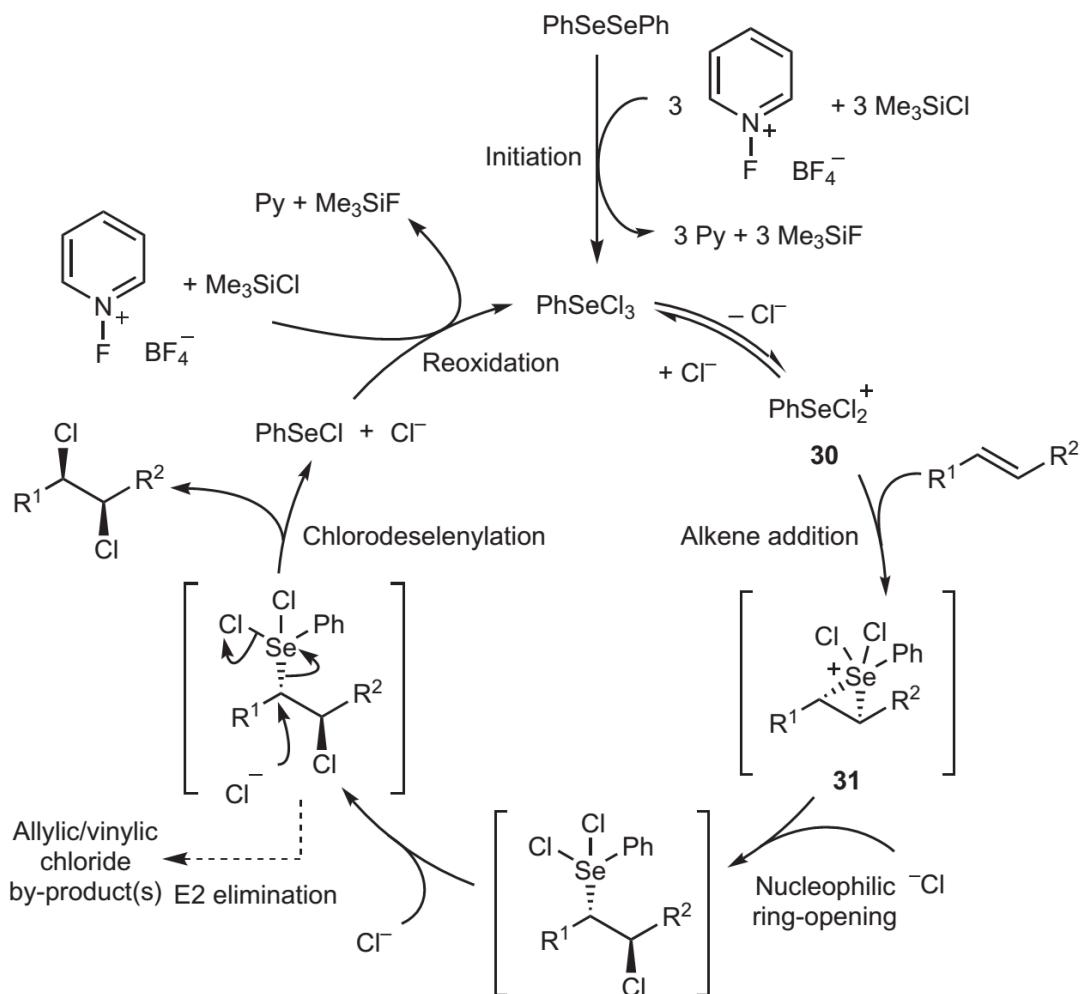

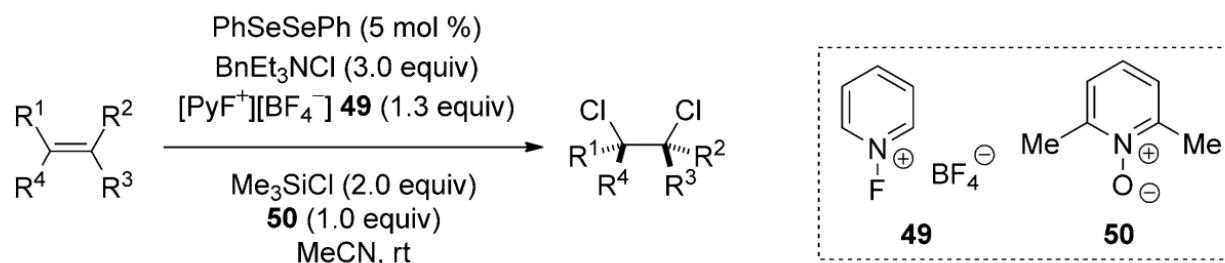

**M = a metal or main group electrophile**

\* Type II<sub>ret</sub>

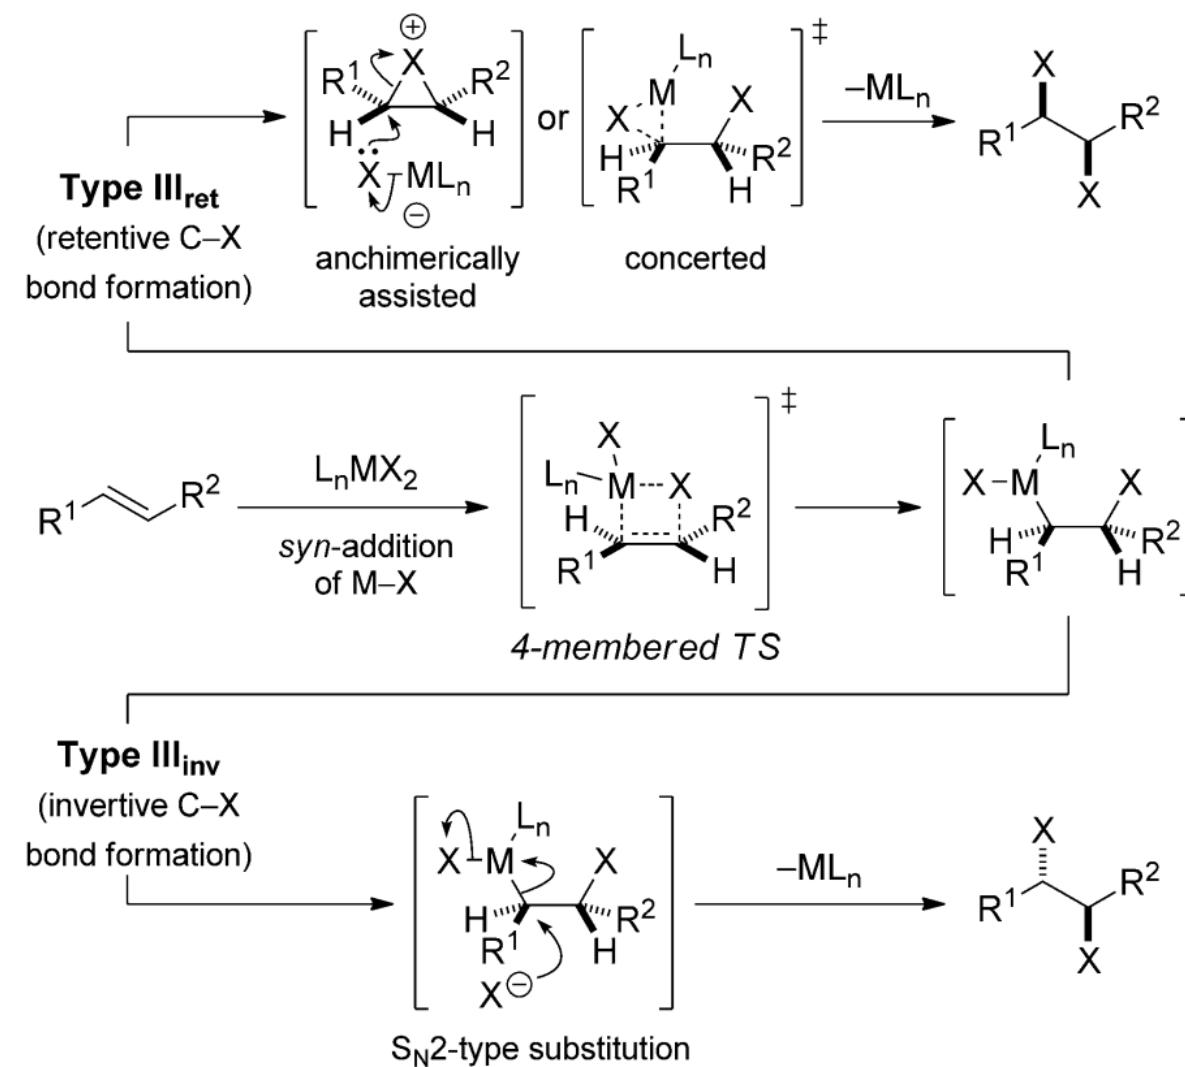

**Scheme 84.** Calculated Type II<sub>ret</sub> mechanism for alkene dibromination with  $\text{CuBr}_2$  and  $\text{LiCl}$  in  $\text{MeCN}/\text{THF}$ .

## \* Type II<sub>inv</sub>

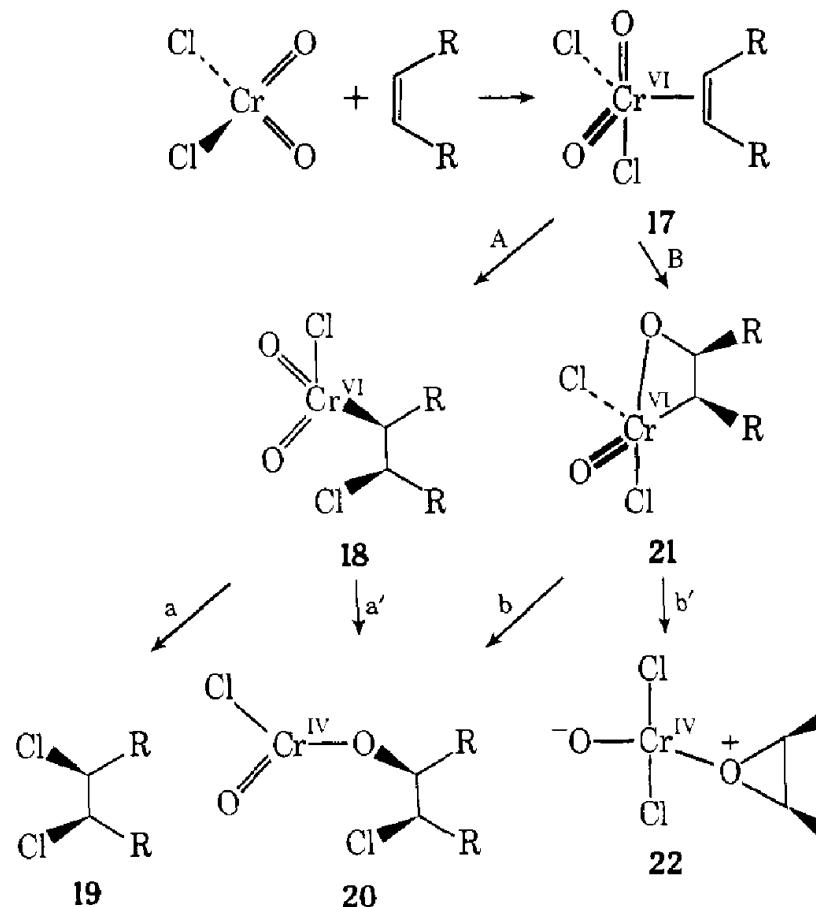

# \* Type III Dihalogenation

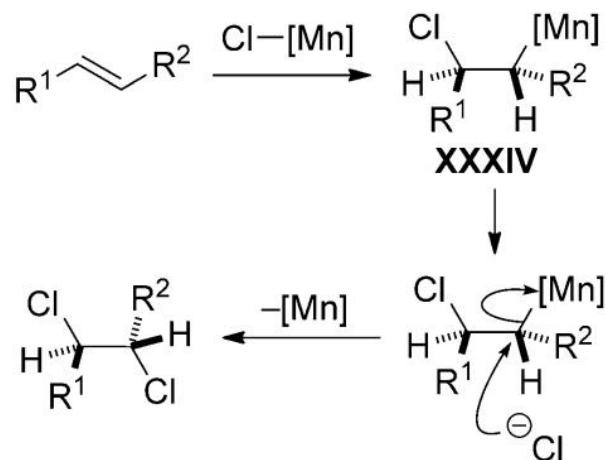

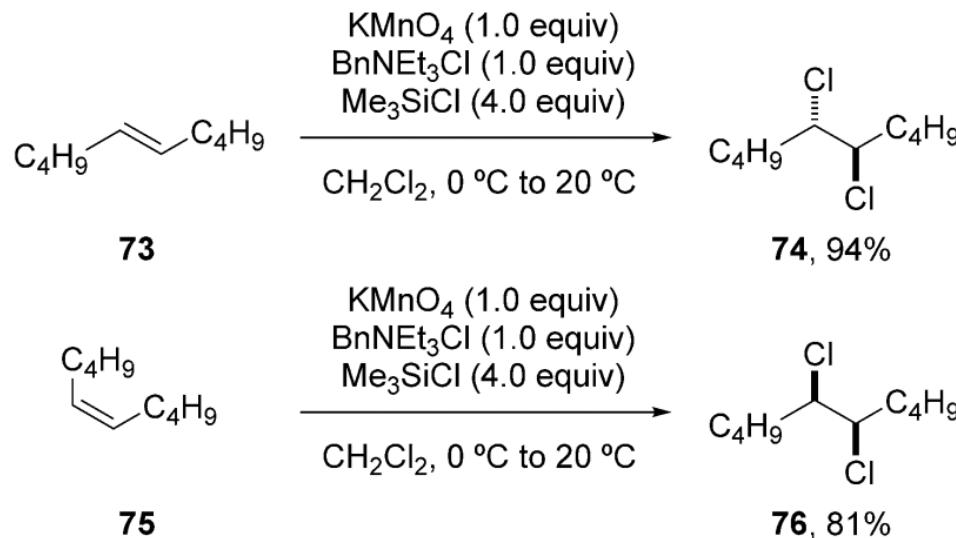

\* Type III<sub>ret</sub>

Chromyl Chloride Oxidations of Olefins. Possible Role of Organometallic Intermediates in the Oxidations of Olefins by Oxo Transition Metal Species

Scheme III. Mechanism Involving Organometallic Intermediates

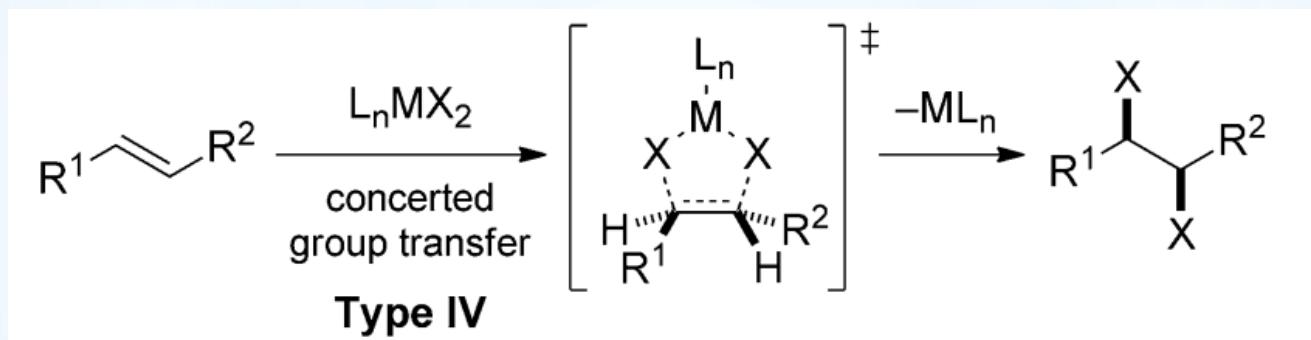

\* Type III<sub>inv</sub>

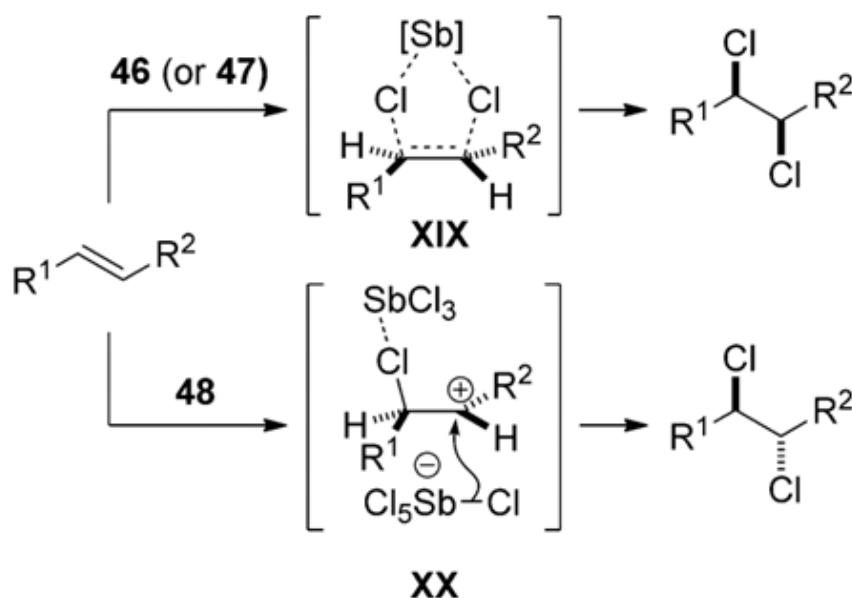

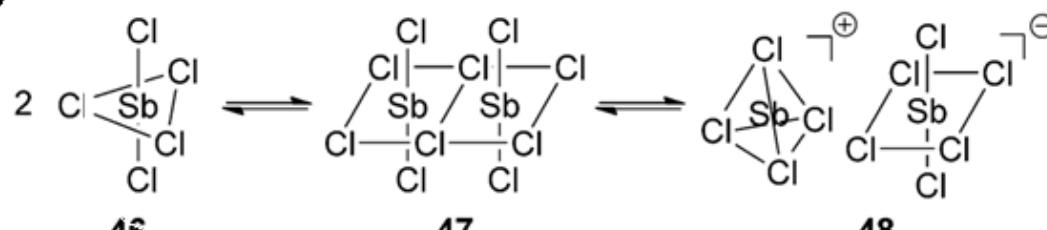

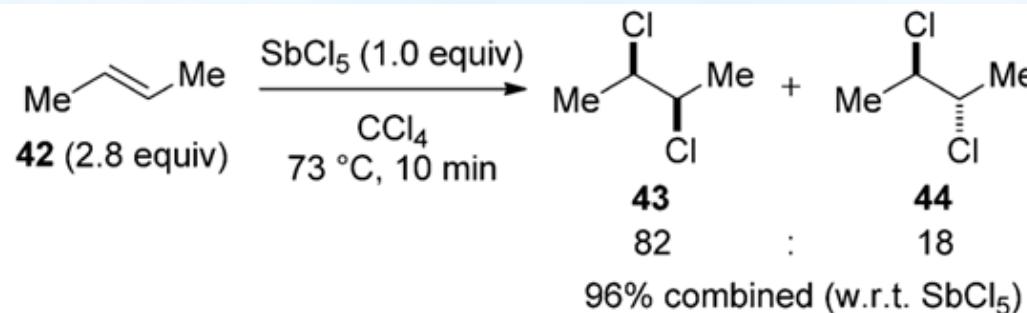

**Scheme 65.** Mechanistic proposal for the *anti*-dichlorination of alkenes by Markó's reagent.

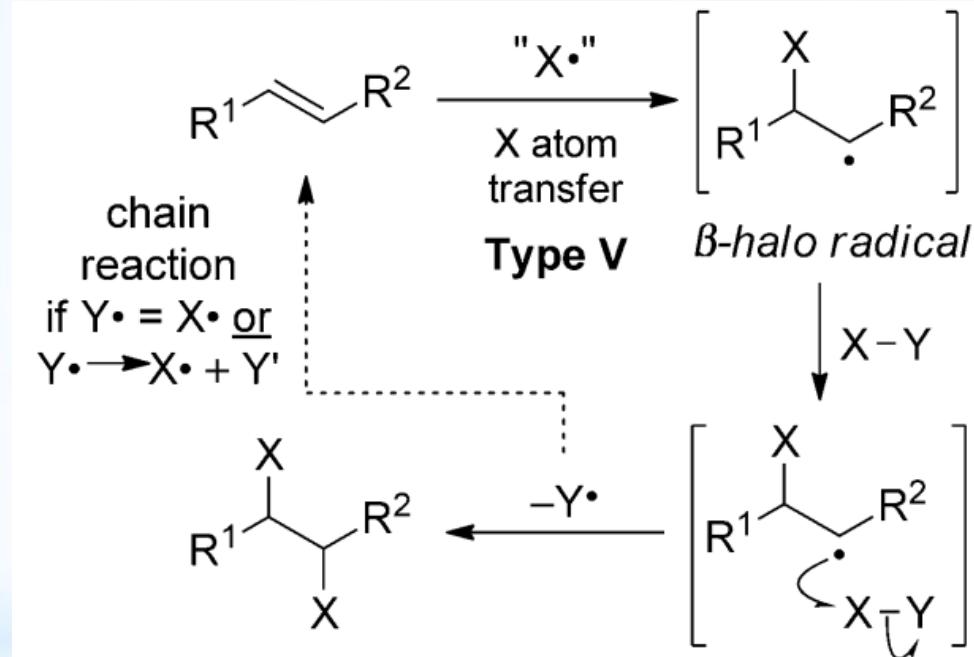

## \* Type IV Dihalogenation

# \* Type IV Dihalogenation

## \* Type V Dihalogenation

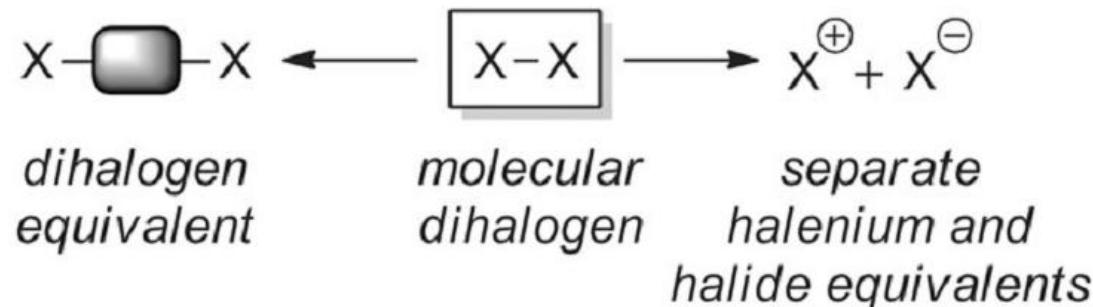

\* **Problem:**

- \* 1) control of regioselectivity in the nucleophilic trapping with halide ion
- \* 2) difficulties in transmitting stereochemical influence from a catalyst covalently bound to the halogen atom
- \* 3) potential for alkene-to-alkene halonium ion transfer processes causing racemization of enantioenriched haliranium ions.
- \* 4) the control of relative configuration is limited, as the reactions are stereoelectronically mandated to deliver antidihalogenated products, with no general means of overturning this selectivity.
- \* 5) a number of these mechanistic proposals are speculative, and some of them lack rigorous experimental or theoretical support.
